Dead Code Elimination

Postscript

Definitions

- ▶ Dead code
 - ▶ *Useless operation*: Not externally visible
 - ▶ *Unreachable code*: Cannot be executed
- ▶ *Critical operation*: (Direct) “Useful operation”
 - ▶ Operation that computes return value
 - ▶ Operation that stores to memory (i.e. is externally visible)
 - ▶ Operation that performs I/O
 - ▶ ...

Two Steps: Step 1

- ▶ Find all directly useful operations and mark them
- ▶ Find all indirectly useful operations and mark them
 - ▶ I.e. those that feed into directly useful operations
- ▶ Iterate until all operations that ultimately feed into directly useful operations have been found and marked

Two Steps: Step 2

- ▶ Remove all operations that remain unmarked

Example #1

```
void swap(int *x, int *y) {  
    int t;  
  
    t = *x;  
    *x = *y;  
    *y = t;  
}
```

Example #2

```
int min(int x, int y) {  
    int r;  
  
    if (x > y) {  
        r = y;  
    } else {  
        r = x;  
    }  
  
    return r;  
}
```

Example #2: 3AC

```
int min(int x, int y) {
    int r;
    int t;

    t = x > y;
    if(t == 0) goto L1;

    r = y;
    goto L2;

L1:
    r = x;

L2:
    return r;
}
```

Example #2: With useless operations removed

```
int min(int x, int y) {  
    int r;  
  
    r = y;  
    r = x;  
  
    return r;  
}
```

- ▶ Marking and removing useless operations uses only dataflow information
- ▶ Must also preserve control flow (i.e. control dependences)
 - ▶ How to identify useful branches?

Handling Control Flow

- ▶ Assume all “jumps” (unconditional branches) are useful
 - ▶ i.e. `goto Lx`
- ▶ What about conditional branches?

Conditional Branches: Example

```
int first_N_sum(int N) {  
    int s = 0;  
  
    for(int i = 1; i <= N; i++)  
        s = s + i;  
  
    return N * (N + 1) / 2;  
}
```

3AC code for conditional branches

```
int first_N_sum(int N) {
    int s = 0;
    int i, t;

    i = 1;
L1:
    t = i <= N;
    if(t == 0) goto L2;

    s = s + i;
    i++;
    goto L1;

L2:
    return N * (N + 1) / 2;
}
```

How do we recognize that the conditional branch is useless in this case?

GCC 8.2 for x86-64 (-O0)

first_N_sum(int):

```
    push    rbp
    mov     rbp, rsp
    mov     DWORD PTR [rbp-20], edi
    mov     DWORD PTR [rbp-4], 0          ; s = 0
    mov     DWORD PTR [rbp-8], 1        ; i = 1
```

.L3:

```
    mov     eax, DWORD PTR [rbp-8]
    cmp     eax, DWORD PTR [rbp-20]
    jg     .L2
    ; s = s + i
    mov     eax, DWORD PTR [rbp-8]
    add     DWORD PTR [rbp-4], eax
    add     DWORD PTR [rbp-8], 1
    jmp    .L3
```

.L2:

```
    mov     eax, DWORD PTR [rbp-20]
    add     eax, 1
    imul   eax, DWORD PTR [rbp-20]
    mov     edx, eax
    shr    edx, 31
    add     eax, edx
    sar    eax
    pop    rbp
    ret
```

GCC 8.2 for x86-64 (-O1)

```
first_N_sum(int):
    test    edi, edi
    jle    .L2
    lea    edx, [rdi+1]
    mov    eax, 1          ; i = 1
.L3:
    add    eax, 1          ; i = i + 1
    cmp    eax, edx
    jne    .L3
.L2:
    lea    eax, [rdi+1]
    imul   edi, eax
    mov    eax, edi
    shr    eax, 31
    add    eax, edi
    sar    eax
    ret
```

GCC 8.2 for x86-64 (-O2)

```
first_N_sum(int):  
    lea    eax, [rdi+1]  
    imul   edi, eax  
    mov    eax, edi  
    shr    eax, 31  
    add    eax, edi  
    sar    eax  
    ret
```

All compiler output examples obtained using the Compiler Explorer.

Conditional Branches

- ▶ A conditional branch is useful only if:
 - ▶ A useful operation depends on it
- ▶ Control dependence
 - ▶ (informal) an operation O is dependent on a branch B if the direction of the branch B affects if O is executed
 - ▶ CFG property

Example of control dependence

```
t = x > y
if(t == 0) goto L1

    r = y;
    goto L2;

L1:
    r = x;

L2:
    return r;
```

The assignments to `r` are dependent on `if(t == 0)`, but `return r` is not

Control dependence in the CFG

Control Dependence: Formal Definition

- ▶ Postdominance
 - ▶ A node n postdominates m if it occurs on all paths from m to EXIT
- ▶ A node k is control dependent on i if:
 - ▶ For a path $i \rightarrow j_0 \rightarrow j_1 \rightarrow \dots \rightarrow k$, k postdominates all j_x
 - ▶ k does not strictly postdominate i

Marking unconditional branches useful

- ▶ If node k contains useful operations,
- ▶ And if k is control-dependent on node i ,
- ▶ Then the (conditional) branch in i is useful.
- ▶ Operationalized as:
 - ▶ If block k contains useful operations
 - ▶ Mark all branches in k 's *reverse dominance frontier* $RDF(k)$ as useful
 - ▶ RDF computed as DF on *edge-reversed* CFG

Dead Code Elimination: High-level algorithm

- ▶ Mark all directly useful operations
- ▶ Repeat until convergence
 - ▶ Mark all indirectly useful operations
 - ▶ Mark all unconditional branches in RDFs of useful operations as useful
- ▶ Remove all unmarked operations
- ▶ Remove empty nodes in CFG / remove all useless control flow

See algorithms in Figure 10.1 and 10.2 in Turczon and Cooper.
