Introduction

SAT Solving

SMT Solvers

Applications to Program Analysis
The Satisfiability (SAT) Problem

Given a formula in propositional logic (variables, true, false, ∧, ∨, ¬, and parentheses), is there an assignment to variables that makes the formula true?

- \((A ∨ B ∨ C) ∧ (¬A ∨ B)\) (conjunctive normal form, CNF)
- \((A ∧ B ∧ C) ∨ (¬A ∧ B)\) (disjunctive normal form, DNF)
- \(A ∧ ¬A\) (CNF)
Solutions

- $(A \lor B \lor C) \land (\neg A \lor B)$
  - $A = \text{true}$ is required in any satisfying assignment ($B$ and $C$ don't matter)
- $(A \land B \land C) \lor (\neg A \land B)$
  - $A, B, C$ all true is one satisfying assignment
  - $A = \text{false}$ and $B = \text{true}$ is another satisfying assignment

- $A \land \neg A$ is obviously unsatisfiable
SAT is NP-Complete

- If the maximum number of variables in a clause of a CNF formula is $k$, we call that problem $k$-SAT
- 2-SAT is solvable in polynomial time
- 3-SAT is NP-complete
  - In worst case, must explore every possible assignment of values to each variable
SAT Problem Sizes

- There are many good SAT solvers now available
  - Based on the Davis–Putnam-Logemann-Loveland (DPLL) algorithm
  - Often enhanced with Conflict-Driven Clause Learning (CDCL)
  - SAT is decidable, if untractable

- Intractability not a hindrance usually
  - Can scale to very large problems
  - Millions of clauses
  - See: The International SAT Competition

- Applied to many hardware and software verification problems

- SAT solvers return:
  - SAT: if a satisfying assignment is found (and the values that satisfy the proposition)
  - UNSAT: if no satisfying assignment exists
The statement \( \neg(A \land B) = (\neg A \lor \neg B) \) is valid, it is true for all values of \( A \) and \( B \).
Proof using a SAT solver

- \( \neg(A \land B) \implies (\neg A \lor \neg B) \)
- \( (\neg A \lor \neg B) \implies \neg(A \land B) \)
- Recall that \( P \implies Q \) can be written as \( \neg P \lor Q \)
  - \( \neg\neg(A \land B) \lor (\neg A \lor \neg B) \)
  - \( \neg(\neg A \lor \neg B) \lor \neg(A \land B) \)
- So we have:
  - \( R = (A \land B) \lor (\neg A \lor \neg B) \)
  - \( S = \neg(\neg A \lor \neg B) \lor \neg(A \land B) \)
- For the proof, we need both \( R \) and \( S \) to be valid
  - If \( R \) is valid, what can we say about the satisfiability of \( \neg R \)?
The Satisfiability of $\neg R$

If $R$ is valid, then $\neg R$ is unsatisfiable!

- To prove a statement using a SAT solver:
  - Convert the statement to propositional logic
  - Negate it, and check for unsatisfiability

- Interesting corollary:
  - If the formula is SAT (implying the statement is false), the values that satisfy the statement are counter-examples
• Volume 4 Facsicle 6 of *The Art of Computer Programming*
• Weissenbacher, Subramanyan, and Malik, Boolean Satisfiability Solvers: Techniques and Extensions
• Barrett, Sebastiani, Sheshia and Tinelli, Satisfiability Modulo Theories
Quantifiers, Theories

- Propositional logic can be extended with quantifiers
  - $\exists$, existential quantifier
  - $\forall$, universal quantifier
  - This is First-order Logic (FOL)
  - FOL is undecidable in general

- Both propositional logic and first-order logic are still boolean

- Can be extended with theories:
  - Arithmetic: adds numbers, operators $+, -, \times$, associativity, commutativity, etc.
  - Functions: adds $f(x)$
  - Bitvectors: model variables containing $n$ bits (where $n > 1$)
• A SMT solver checks for satisfiability *in a theory*
  • Can think of statements as propositional logic + theory
• Allows construction of “richer” statements
  • Can formulate propositions over integers, reals, etc.
  • Can use operators like +, −, ×, etc.
• Example: $\forall x, y \ x > y \implies x + 1 > y + 1$
  • True over integers ($\mathbb{Z}$)
  • False over machine integers/bitvectors
• Some theories are decidable
  ● Presburger arithmetic
• Most theories are undecidable
• However, some theories undecidable in general are decidable
  over quantifier-free fragments
• So, results of a SMT solver can be:
  ● SAT
  ● UNSAT
  ● Don’t know (or infinite loop)
Outline

Introduction

SAT Solving

SMT Solvers

Applications to Program Analysis
Some SMT solvers

- Microsoft Z3
  - Available online at rise4fun/Z3
  - Available in most Linux distributions
- CVC4
- Yices
- Many more...
The SMT-LIB language

- Common input/output language for most SMT solvers
  - Some solvers support their own language as well
- Lisp-like
- Documented at smtlib.org
- Allows easy switching between solvers
  - We will use Z3 for the most part
Let's encode $\neg R$ from the previous example:

\[
\begin{align*}
&(\text{declare-fun } B () \text{ Bool}) \\
&(\text{declare-fun } A () \text{ Bool}) \\
&(\text{assert (not (or (and A B) (not A) (not B))))) \\
&(\text{check-sat})
\end{align*}
\]

And we run it:

\[
\begin{align*}
&\$ \text{ z3 p1.smtlib} \\
&\text{unsat}
\end{align*}
\]
Alternative: Python library

#!/usr/bin/env python3

from z3 import *

s = Solver()
A, B = Bools('A B')

R = Or(And(A, B), Or(Not(A), Not(B)))
notR = Not(R)

s.add(notR)
print(s.check())
print(s.check())
print(s.sexpr())  # prints the SMTLIB code

See: Bjørner et al., Programming Z3, for a nice introduction to programming Z3 using Python.
The Constraint Satisfaction Problem seeks to find an assignment of values to variables subject to constraints.

- Each variable has a domain of values.
- Pick a variable, assign it a value, subject to constraints.
- If all variables can be assigned values, SAT else backtrack.

For SAT in propositional logic:

- Two values, True and False.
- Constraint: formula must evaluate to true.
Other Problems

- Dennis Yurichev’s free book “SAT/SMT by Example” is a wonderful collection of examples
  - Minesweeper
  - Sudoku
  - Test case generation, etc.
Outline

Introduction

SAT Solving

SMT Solvers

Applications to Program Analysis
SMT Solvers in Program Analysis

- Express program behaviour in some logic
- Express program property in that logic
- Check if the property holds (i.e. is valid)
```c
int min(int a, int b) {
    if(a < b)
        return a;
    else
        return a;
}

int x, y, r;
r = min(x, y);
assert(r == x || r == y);
assert(r <= x && r <= y);
```

- These assertions test that `min` always returns the minimum of `x` and `y`
- But `assert` executes at runtime
- We will seek to prove statically:
  - `∀x,y(min(x, y) = x ∨ min(x, y) = y) ∧ (min(x, y) ≤ x ∧ min(x, y) ≤ y)`
  - over all program paths
from z3 import *

s = Solver()
a, b, ret = Ints('a b ret')
ret = If(a < b, a, a)
#ret = If(a < b, a, b) # correct
cond = And(Or(ret == a, ret == b), And(ret <= a, ret <= b))
s.add(Not(cond))
print(s.sexpr())

if s.check() == sat:
    print("Incorrect. Counterexample: ", s.model())
else:
    print("Correct")

Output:

... Incorrect. Counterexample:  [b = 0, a = 1]
• If $A$ is a source program and $B$ is the compiled version, we would like to prove that $A = B$
  • This is called *translation validation*
  • What I’ve been doing for your submissions

• Undecidable, in general

• Not interesting only to compiler writers
  • If you take a piece of code and refactor it, did you break anything?
The test case \((1, 3)\) is not sufficient to exercise all paths in the program

- And it misses the bug!

Can we find test cases to exercise all paths in the program?
SMT solvers are a marvellous piece of technology

Learn to use one!
